

EXERCISE SESSION 13

The first part of this exercise session will help you getting familiar with latent variable models. First, download the files from the folder *Additional material*. It contains the script file (.py) and the Jupyter notebook (.ipynb) for a latent variable model. Table 1 presents the estimation results of such model. Go through the script file or the notebook in detail and perform the following tasks:

1. Identify the attitude that is modeled as a latent variable.
2. Identify the indicators that are considered.
3. Identify the structural equations for both the choice and the latent variable models.
4. Identify the measurement equation for both the choice and the latent variable models.
5. Interpret the parameters of the model.

Please notice that such models take longer to be estimated than the models we typically see in the labs. This is why we provide the estimates and ask you to analyze carefully the implementation.

Exercise 1 An analyst is interested in modeling a mode choice problem between car and public transportation (PT) in a large city taking into account the effect of attitudes such as discomfort of using public transportation (*AttAntiPT*) and environmental concern (*AttProEnv*). In this context, an integrated choice and latent variable model is appropriate in order to account for the effects of the attitudes on mode choice.

The analyst is designing the survey for the data collection. She will collect information about the characteristics of the individuals and the observed attributes of the alternative modes, which are exogenous explanatory variables, as well as *attitudinal indicators* for the latent variables model. To obtain these indicators, she proposes statements and asks the respondent to position himself about them, using a scale ranging from -2 (totally disagree) to 2 (totally agree). Two indicators related to each attitude are collected. The two indicators related to the attitude *AttAntiPT* are noted I_{1n} and I_{2n} and the two indicators related to *AttProEnv* are noted I_{3n} and I_{4n} .

1. In the specification of the choice model the analyst has considered the effect of: i) cost, ii) time, iii) number of children, iv) frequency of public transportation (Figure 1). Complete the diagram in Figure 1 in order to integrate the effect of the two latent variables in the choice model. We assume that the latent variables are not explained by the variables i)-iv). Make sure to use appropriate shapes and arrows and explain the drawing convention, i.e., what do the different shapes and arrows represent.

2. Update your diagram once more (use Figure 2), assuming that people with high education level and people who own a bike have a pro-environmental attitude, while people with low education level and owning more than one car have an attitude against PT.
3. Write down the structural equations corresponding to the a) *choice* and b) *latent variable* models, accordingly. Consider the specification of the updated diagram obtained in sub-question 2.
4. Write down the measurement equations corresponding to the a) *choice* and b) *latent variable* models, accordingly. Take into account that the collected indicators are discrete.
